0.2 Obiettivo

Seguiremo il testo “Applied Spatial Data Analysis with R” di Bivand Pebema e Gómez-Rubio (vedi link sopra)

0.3 Giornata 1

Ripasso, analisi esplorativa dei dati per verifiche presupposti

Parte teorica (~1 ora):

- Richiamo sulle statistiche descrittive, distribuzioni, trasformazioni, sistemi di riferimento
- Richiamo geostatistica: variabili regionalizzate, autocorrelazione spaziale
- Il variogramma: definizione, semivarianza, sperimentale vs modello, legame con la continuità spaziale.

Parte pratica (~90 min):

- Caricamento di un dataset ambientale (es. concentrazioni suolo, misure vegetazione, temperatura)
- Exploratory Data Analysis: mappe puntuali, geolocalizzazione, scatter plot, istogrammi
- Calcolo dell'autocorrelazione (es. indice di Moran) e del variogramma sperimentale
- Discussione: “Cosa ci dice il variogramma? Quali sono i punti deboli (campionamento, anisotropia, non stazionarietà)?”
- Interpolazione Kriging, ordinaria, universale, co-kriging...

Riassunto (~30 min):

- Assegnazione di un esercizio da consegnare
- Discussione aperta su cosa ci si aspetta in diversi ambiti ARPA (suolo, meteo, inquinamento, ecc)

0.4 Giornata 2

- Calcolo dell'autocorrelazione (es. indice di Moran) e del variogramma sperimentale - dati del veneto - esercizio da consegnare
- Discussione: “Cosa ci dice il variogramma? Quali sono i punti deboli (campionamento, anisotropia, non stazionarietà)?”
- Interpolazione (kriging) e stima spaziale - cokriging, block kriging, collocated kriging, global vs local kriging, indicator kriging
- Introduzione alla validazione

Riassunto (~30 min):

- Assegnazione di un esercizio da consegnare
- Discussione aperta su cosa ci si aspetta in diversi ambiti ARPA (suolo, meteo, inquinamento, ecc)

0.5 Giornata 3

- Simulazioni (tipo Monte Carlo)
- valutazione dell'incertezza e applicazioni avanzate

0.14 Modelli Multivariati - co-kriging

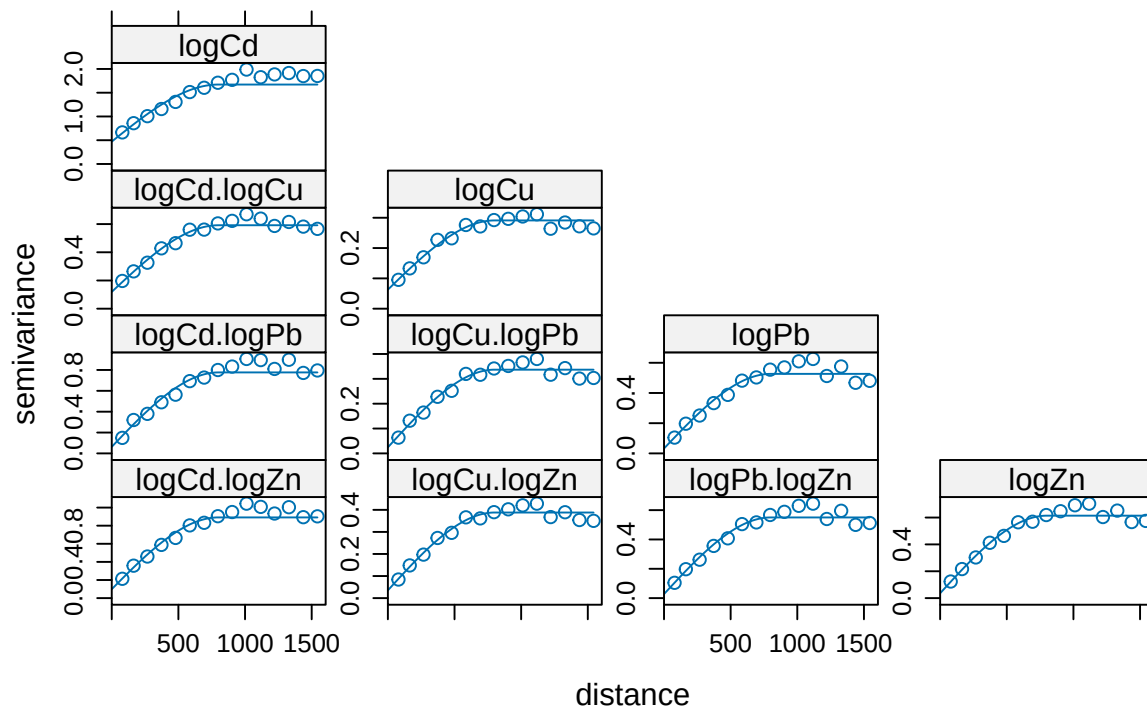

I modelli multivariati considerano più variabili dipendenti, ovvero variabili coregionalizzate (o coregionalized variables) che sono variabili che vengono analizzate congiuntamente, perché correlate tra loro nello spazio. L'idea è che una variabile possa "aiutare" a stimare un'altra, se condividono una struttura di dipendenza spaziale.

c'è correlazione?
`cor(as.data.frame(meuse)[c("cadmium", "copper", "lead", "zinc")])`

```
##          cadmium    copper    lead    zinc
## cadmium 1.0000000 0.9254499 0.7989466 0.9162139
## copper   0.9254499 1.0000000 0.8183069 0.9082695
## lead     0.7989466 0.8183069 1.0000000 0.9546913
## zinc     0.9162139 0.9082695 0.9546913 1.0000000
```

se si allora possiamo creare una struttura multivariata
`g <- gstat(NULL, "logCd", log(cadmium) ~ 1, meuse)`
`g <- gstat(g, "logCu", log(copper) ~ 1, meuse)`
`g <- gstat(g, "logPb", log(lead) ~ 1, meuse)`

0.17 Collocated Cokriging

Due condizioni differenti quando abbiamo una variabile indipendente disponibile sia nei punti campione sia nei punti che vogliamo stimare (la griglia). Come nel caso della distanza dai corsi d'acqua nel caso Meuse

```
#Crea un oggetto gstat per log(zinc) nel dataset meuse.
g.cc <- gstat(NULL, "log.zinc", log(zinc) ~ 1, meuse, model = v.fit)
# v.fit è il modello di variogramma per log(zinc) usato prima.
# ~1 indica kriging ordinario / media costante.
# A questo punto hai un modello geostatistico univariato
meuse.grid$distn <- meuse.grid$dist - mean(meuse.grid$dist) + mean(log(meuse$zinc))
# Crea una nuova variabile distn sulla griglia di predizione.
# È centrata e scalata per avere la stessa media di log(zinc).
# L'idea: usare questa variabile come secondaria nel cokriging

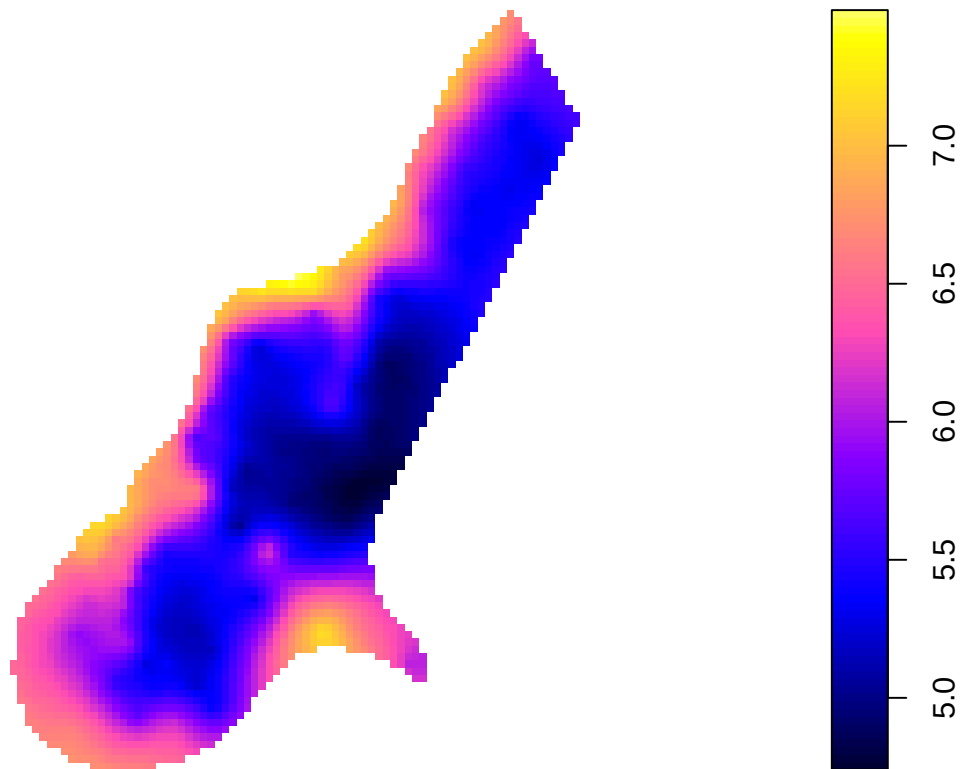

##### # Adeguamento del variogramma per distn
vd.fit <- v.fit
# Copia il variogramma originale v.fit.
# Modifica il sill (psill) proporzionalmente al rapporto tra varianze della nuova variabile e dello
# Questo genera un variogramma sintetico per distn coerente con log(zinc).
vov <- var(meuse.grid$distn)/var(log(meuse$zinc))
vd.fit$psill <- v.fit$psill * vov

# Aggiunge distn come nuova variabile gstat
g.cc <- gstat(g.cc, "distn", distn ~ 1, meuse.grid, nmax = 1, model = vd.fit, merge = c("log.zinc",
# nmax = 1 significa considerare solo il vicino più prossimo per la variabile secondaria
# merge = c("log.zinc", "distn") combina le strutture dati per il cokriging

##### Variogramma incrociato per il cokriging
vx.fit <- v.fit
vx.fit$psill <- sqrt(v.fit$psill * vd.fit$psill) * cor(meuse$dist, log(meuse$zinc))
g.cc <- gstat(g.cc, c("log.zinc", "distn"), model = vx.fit)
x <- predict(g.cc, meuse.grid)

0.18 Global vs local kriging

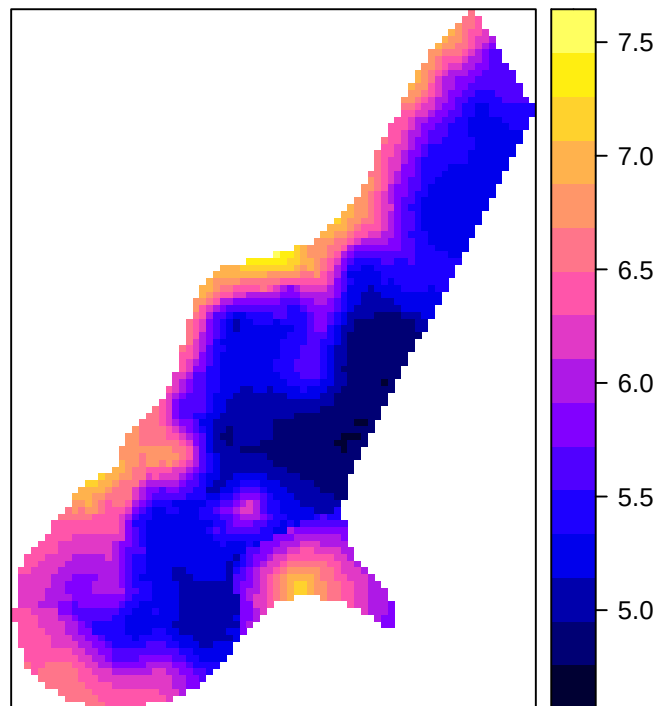

Global kriging stima valori spaziali assumendo una struttura di covarianza su tutta l'area (trend globale), usa dunque tutte le osservazioni mentre local kriging adatta i pesi e la struttura di covarianza a vicinanze limitate, catturando variazioni spaziali locali. Globale può diventare pesante computazionalmente

```
# Local kriging: nmax = numero massimo di vicini considerati
# Qui consideriamo solo i 5 vicini più prossimi per ogni predizione
lk <- gstat(NULL, "log.zinc", log(zinc) ~ 1, meuse, model=v.fit, nmax=5)
# Predizione
pred <- predict(lk, meuse.grid)

Local Ordinary Kriging (nmax=5)

0.19 Block kriging

Le osservazioni $Z(s_i)$ sono considerate come misurate in punti specifici. Il kriging di un valore con dimensione fisica pari a quella delle osservazioni si chiama point kriging (kriging puntuale). Al contrario, il block kriging stima medie su aree o volumi più grandi.

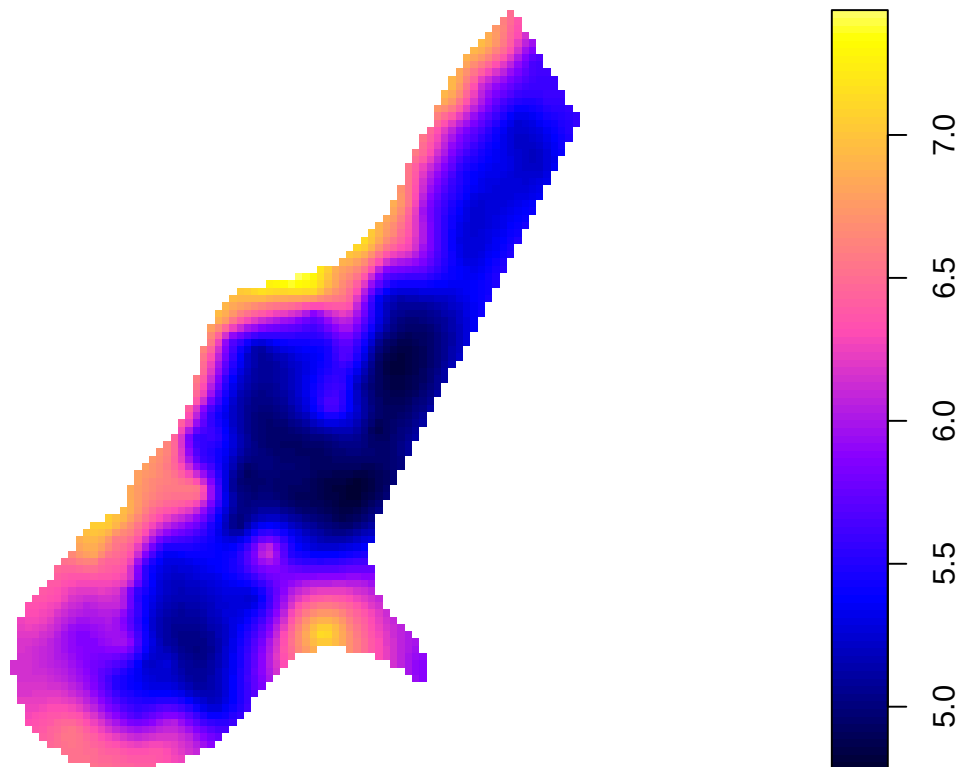

Il point kriging di solito mostra errori di stima più elevati. Questo avviene perché le osservazioni singole presentano maggiore variabilità.

Quando invece si stimano medie su aree più estese (block kriging), gran parte della variabilità interna ai blocchi si media, e quindi le medie dei blocchi hanno errori di stima più bassi, pur mantenendo visibili i pattern spaziali, purché i blocchi non siano troppo grandi.

```
lz.ok <- krige(log(zinc) ~ 1, meuse, meuse.grid, v.fit, block = c(40, 40))
```

0.20 Kriging stratificato/indicator?

Quando è disponibile una variabile categorica che suddivide l'area di interesse in un certo numero di aree disgiunte, ad esempio classi di uso del suolo o qualche altro fattore, potremmo voler applicare il kriging separatamente per le diverse classi. Questo approccio si chiama stratified kriging (kriging stratificato).

Il motivo per applicare il kriging per classe è che la struttura di covarianza (semivariogramma) può essere diversa tra le classi. A differenza del universal kriging con un predittore categorico, in questo caso non si assume alcuna correlazione tra i residui delle diverse classi. Altro esempio: temperatura in zone urbane vs temperatura in zone non urbane

```
library(sp)
# Interpolazione iniziale della variabile categoriale part.a
meuse$part.a <- idw(part.a ~ 1, meuse.grid, meuse, nmax = 1)$var1.pred
```

```
## [inverse distance weighted interpolation]
```

```
# [interpolazione ponderata per distanza inversa]
# Qui qualsiasi interpolazione va bene, perché stiamo praticamente usando
# il primo vicino più prossimo come predittore.
```

```
# Approccio più robusto: usare overlay per assegnare valori della griglia
meuse$part.a <- over(meuse, meuse.grid)$part.a
# Questo metodo ignora eventuali osservazioni non coperte dalla griglia.
```

```
# Ora possiamo eseguire il kriging per ciascun sottodominio,
# memorizzare i risultati in x1 e x2, e poi unirli con rbind
# nella loro rappresentazione non spaziale.
```

```
# Kriging ordinario per il primo sottodominio (part.a == 0)

0.21 Kriging trend con variabile discreta

Diverso da indicator kriging ... modella il trend come dipendente dalla categoria soil, e poi stima un **unico** variogramma dei residui; indicator kriging divide i variogrammi in funzione dei punti presenti per ogni classe.

# calcolo della varianza back-transformata

0.23 Validazione

La varianza mi stima l'affidabilità, ma una vera validazione richiede di confrontare il risultato con dati oggettivi misurati. Unico modo è quello di separare il dataset in un set di misure da usare per il modello ed un set misure da usare per la validazione. Importante che i due set siano entrambi rappresentativi della distribuzione (non biased).

cross-validazione: leave-one-out o k-fold.

attenzione che "leave-one-out" richiede molto tempo in quanto esegue kriging tante volte quanti sono i punti del dataset

```
cv <- krige.cv(log(zinc) ~ 1, meuse, model = v.fit)

0.24 Indicatori di accuratezza

Alla fine devo avere degli indicatori per confrontare “quale metodo funziona meglio”

# Residui standardizzati
MSDR <- mean(cv$zscore^2)

results <- data.frame(ME, RMSE, MSDR)
